1. Abstract

This report summarizes the technical work completed during a Product Marketing Engineering internship within the Low Power Connectivity Solutions organization at Texas Instruments. The internship focused on developing practical knowledge of Bluetooth Low Energy (BLE), BLE Mesh networking, Zephyr Real-Time Operating System (RTOS), over-the-air (OTA) firmware updates, and Texas Instruments' low-power wireless microcontrollers. This knowledge was applied through hands-on embedded development and the creation of developer-facing technical content.

The primary internship project consisted of a three-part technical video series covering an introduction to BLE Mesh, the development of a Zephyr-based BLE demonstration, and a Zephyr BLE OTA demonstration. These projects required researching wireless technologies, modifying and testing embedded software, working with the CC2340R53 wireless microcontroller and TI development tools, troubleshooting implementation challenges, and translating technical concepts into concise educational resources. Additional activities included technical presentations, cross-functional collaboration, and customer-focused sales simulations. Overall, the internship strengthened my understanding of wireless embedded systems while developing my ability to communicate engineering concepts to both technical and customer-facing audiences.

2. Background

The continued growth of Internet of Things (IoT) devices has increased the need for wireless communication technologies that provide reliable connectivity while maintaining low power consumption. Bluetooth Low Energy (BLE) is commonly used in embedded applications where devices must communicate wirelessly while operating within limited power and resource constraints. In addition to traditional point-to-point BLE communication, Bluetooth Mesh extends Bluetooth technology to support many-to-many communication across larger networks. This allows devices to relay information throughout a network and supports applications such as building automation, smart lighting, and infrastructure monitoring.

Alongside developments in wireless communication, embedded software platforms have continued to evolve. The Zephyr Real-Time Operating System (RTOS) provides an open-source development environment for resource-constrained embedded devices and includes support for technologies such as Bluetooth LE. Developing with Zephyr requires an understanding of both embedded software concepts and the underlying hardware being controlled. Developers must be able to configure applications, modify existing examples, interface with hardware peripherals, build and flash firmware, and verify communication between embedded devices and external applications.

Firmware maintenance is another important consideration for connected embedded systems. Over-the-air (OTA) updates allow firmware to be transferred to a deployed device without requiring a physical programming connection. This capability can simplify maintenance and allow functionality or firmware revisions to be deployed after a product has entered service. Implementing OTA functionality introduces additional considerations involving firmware

images, wireless transfer, device management, and verification that the updated firmware is successfully executing.

Texas Instruments' Low Power Connectivity Solutions organization develops wireless microcontrollers and supporting software intended for these types of connected applications. During this internship, work primarily involved the CC2340R53 wireless microcontroller and the surrounding TI and Zephyr development ecosystems. Product Marketing Engineers operate between the technical development of these products and the developers or customers evaluating them. This requires not only understanding the underlying technology, but also determining how technical information can be communicated through demonstrations, presentations, videos, and other developer-facing resources.

The primary project completed during this internship addressed developer education surrounding BLE Mesh and Zephyr development. The work progressed from researching wireless technologies to developing and validating embedded demonstrations and ultimately translating those demonstrations into technical educational content. This combination of embedded development and technical communication provided practical experience with wireless systems while demonstrating how engineering knowledge can be used to support the adoption of low-power connectivity solutions.

3. Objectives

As a Product Marketing Engineering Intern, my primary objective was to strengthen my technical understanding of low-power wireless connectivity while learning how engineering knowledge is translated into resources for developers and customers. Throughout the internship, this required developing knowledge of unfamiliar wireless technologies, applying that knowledge through embedded development and demonstrations, and communicating technical concepts in a concise and accessible manner. The internship also provided opportunities to work with engineers across multiple disciplines and better understand the relationship between engineering, product marketing, and customer needs.

3.1 Develop Technical Knowledge of Wireless Connectivity

The first objective was to develop a stronger understanding of wireless communication technologies relevant to Texas Instruments' Low Power Connectivity Solutions portfolio. This included Bluetooth Classic, Bluetooth Low Energy (BLE), BLE Mesh, Zephyr RTOS, and over-the-air (OTA) firmware updates. Particular emphasis was placed on understanding how these technologies operate within embedded systems and how they are implemented using TI wireless microcontrollers. Research into the CC2340 and CC2755 device families further supported the technical knowledge required for the primary internship projects.

3.2 Apply Embedded Systems Knowledge Through Hands-On Development

A second objective was to move beyond technical research by applying newly acquired knowledge through hands-on embedded development. This included working with the CC2340R53 wireless microcontroller, configuring and modifying existing BLE and Zephyr examples, using TI development hardware and software, and validating changes through functional demonstrations. These activities developed my familiarity with real embedded

development workflows while reinforcing concepts learned through technical investigation.

3.3 Develop Developer-Facing Technical Resources

A major objective of the internship was to translate technical knowledge into educational resources that could assist developers evaluating or implementing TI connectivity solutions. The primary project evolved into a three-part technical video series covering BLE Mesh fundamentals, development of a Zephyr BLE demonstration, and Zephyr BLE OTA functionality. Each project required balancing technical accuracy with accessibility so that complex concepts and development workflows could be presented clearly without removing the engineering detail necessary for a developer audience.

3.4 Strengthen Technical Communication and Customer-Facing Engineering Skills

Product Marketing Engineering requires technical knowledge to be communicated differently depending on the intended audience. An additional objective was therefore to improve my ability to explain engineering concepts through presentations, demonstrations, technical discussions, and customer-facing interactions. Two sales simulations conducted at different points during the internship provided opportunities to practice identifying customer needs, communicating relevant technical information, and explaining the value of TI solutions. The second simulation also provided a way to evaluate growth in both technical understanding and customer communication over the course of the internship.

3.5 Gain Experience Working Across Engineering and Business Functions

The final objective was to develop a broader understanding of how Product Marketing Engineering operates within a semiconductor organization. Throughout the internship, I met individually with 20 people across different roles, teams, and technical areas at Texas Instruments. These discussions included perspectives from applications engineering, systems engineering,

product marketing engineering, and multiple connectivity organizations. By learning how different teams contribute to product development and customer support, I gained a better understanding of how technical knowledge, product strategy, developer needs, and business considerations come together within the semiconductor industry.

4. Methodology

The technical work completed throughout this internship followed an iterative process of research, hands-on development, testing, technical review, and communication. At the beginning of the internship, I had no previous experience with wireless connectivity technologies such as Bluetooth Low Energy (BLE), BLE Mesh, or Zephyr. Therefore, each major assignment required first developing the technical knowledge necessary to understand the topic before determining how that knowledge could be applied and communicated through a developer-facing resource.

The primary project consisted of three technical video assignments covering BLE Mesh, Zephyr BLE development, and Zephyr BLE over-the-air (OTA) functionality. Each assignment was initially provided primarily as a project title and high-level objective, with limited direction regarding the specific technical content or implementation approach. Determining the scope and approach was therefore part of the project itself. When questions arose, I was frequently encouraged to first develop my own recommendation or solution rather than being provided with a predefined answer. This required independent technical investigation, experimentation, and engineering judgment throughout the internship.

An additional part of this process was learning how to seek technical support effectively. As the projects became more specialized, I had to determine which engineers had the knowledge relevant to a particular problem and how to communicate the issue clearly enough to receive useful guidance. Over time, I became more comfortable identifying what I already knew, isolating what I did not understand, and asking more concise technical questions. This became particularly important during the Zephyr and OTA projects, where troubleshooting sometimes required knowledge from engineers with different areas of expertise.

As the internship progressed, the projects required increasing levels of hands-on development

and troubleshooting. The first project emphasized learning and communicating BLE Mesh concepts, the second required modifying and validating a Zephyr BLE application on the CC2340R53, and the third expanded this work into OTA firmware development and troubleshooting. Feedback and technical review were incorporated throughout each project to improve both technical accuracy and the effectiveness of the final developer-facing content.

4.1 Technical Investigation and Knowledge Development

The first stage of the internship focused on developing a technical foundation in wireless connectivity. Because I entered the internship without previous experience in wireless communication, initial research began with Bluetooth fundamentals before progressing into BLE, BLE Mesh, Zephyr RTOS, and OTA firmware updates. Technical documentation, training materials, example applications, presentations, and discussions with engineers were used to develop this knowledge.

Early assignments were used to reinforce these concepts and establish an understanding of the Low Power Connectivity Solutions portfolio. I researched differences between Bluetooth Classic and BLE, common BLE applications, low-power communication concepts, and the CC2340 device family. As the primary projects progressed, research expanded to the CC2755 family and the relationship between TI hardware, Zephyr, and the supporting developer ecosystem. The final TI presentation reflected this progression as a deep dive into Zephyr, BLE, BLE Mesh, and the CC2340 and CC2755 device families.

Technical investigation continued throughout the internship rather than occurring only at the beginning of each assignment. BLE Mesh required understanding network architecture and the roles of Proxy, Relay, Friend, and Low Power Nodes, along with scalability, security, and low-power operation. Zephyr required learning a new embedded development environment and

Bluetooth software stack, while the final project introduced OTA firmware updates and device-management concepts. Each new topic built on knowledge acquired during the previous project and required progressively greater technical depth.

Learning to locate information efficiently also became part of the methodology. Not every technical question could be answered through a single document or example, and different engineers specialized in different portions of the development process. I learned to first investigate a problem independently, identify the specific point at which I was blocked, determine who was most likely to have relevant experience, and then communicate the problem concisely. This represented an improvement from earlier in the internship, when I sometimes continued troubleshooting independently longer than necessary before seeking assistance.

4.2 BLE Mesh Research and Technical Content Development

The first major video project was assigned with the high-level objective of creating an "Introduction to BLE Mesh" video. At the time the project was assigned, I had no prior knowledge of BLE Mesh and had only recently begun learning about wireless connectivity. No predefined technical outline was provided identifying what should be included. Before developing the resource, I therefore had to independently learn BLE Mesh and determine which concepts would be necessary for a developer or customer encountering the technology for the first time.

Research focused on understanding how BLE Mesh extends traditional BLE communication and identifying the concepts required to explain a mesh network accurately. The final technical content included the roles of Proxy, Relay, Friend, and Low Power Nodes; network scalability; message relaying; security; and applications including building automation, grid infrastructure, and smart lighting. The project also required researching TI's BLE Mesh

offering and available developer resources, including hardware capabilities, SimpleLink resources, training materials, and engineering support.

A major challenge was determining the appropriate level of technical detail. The purpose of the video was not to reproduce a datasheet or lengthy technical training module, but to give developers enough information to understand BLE Mesh, recognize relevant applications, understand TI's offering, and know where to begin. This required repeatedly evaluating which details were essential and which could be removed without compromising technical accuracy.

The presentation used to develop the video underwent approximately eight rounds of review and revision before the content and organization reached their final form. Feedback addressed technical accuracy, organization, messaging, and the amount of information presented. Because reviewers occasionally emphasized different aspects of the project, I also learned that receiving feedback did not necessarily mean that every recommendation should be implemented exactly as suggested. Instead, I became more comfortable evaluating feedback, determining whether a change supported the objective of the resource, and explaining the reasoning behind decisions when necessary.

After the technical content, presentation, and narration were finalized, the video proceeded through TI's internal submission process and was submitted through JIRA for publication. The experience established a development and review process that I was able to apply more efficiently to the subsequent Zephyr projects.

4.3 Zephyr BLE Embedded Development and Demonstration

The second major project shifted from primarily researching and communicating a wireless technology to developing a hands-on embedded demonstration using Zephyr and the CC2340R53. The objective was to demonstrate how an existing Zephyr BLE application could

be modified to create additional functionality and provide developers with a concise example of the development workflow.

Development began with the existing Zephyr Bluetooth LE Peripheral example. The application was modified so that the onboard LED of the CC2340R53 development hardware could be controlled wirelessly through the TI SimpleLink Connect mobile application. The device name was changed to “Zephyr Bluetooth Demo” so that it could be easily identified within the mobile application.

The source code was then modified to incorporate GPIO functionality. This included adding the Zephyr GPIO header, identifying the LED through the device tree alias, and creating the GPIO specification necessary to interact with the onboard LED. Additional modifications connected the LED behavior to a writable BLE characteristic so that a value sent wirelessly from the mobile application could produce a physical response on the development board.

The modified application was built and flashed to the CC2340R53 using the XDS110 development hardware. The SimpleLink Connect application was then used to locate the device, connect to it, navigate to the appropriate characteristic, and write a value to verify the wireless LED-control functionality. The completed demonstration showed the process of moving from an existing Zephyr example to a customized BLE application rather than simply executing unchanged example code.

Development also required significant troubleshooting of the surrounding software environment. A laptop failure resulted in Linux being wiped and reinstalled, after which an OpenOCD issue prevented the normal development workflow from operating correctly. I independently investigated the OpenOCD problem for approximately one day and was able to restore functionality. Additional VS Code integration issues required further investigation with

the team. These challenges provided experience distinguishing between problems caused by application code and those originating from the toolchain or development environment.

The troubleshooting process also reinforced the importance of knowing when and how to request assistance. Earlier in the internship, I was more likely to continue investigating a blocker independently. During this project, I became more aware of the point at which additional troubleshooting was no longer the most efficient approach and learned to approach coworkers with a concise explanation of the behavior observed, the steps already attempted, and the specific question that remained unresolved.

By the end of the internship, the completed Zephyr BLE demonstration had been submitted through JIRA. The final demonstration provided a practical example of modifying embedded software, flashing the resulting firmware, establishing BLE communication, and controlling hardware through a wireless interface.

4.4 Zephyr BLE OTA Development and Troubleshooting

The third major project extended the Zephyr work into over-the-air firmware updates. Unlike the previous project, the objective was not simply to modify application behavior, but to demonstrate how firmware on a wireless microcontroller could be updated without requiring the device to remain physically connected to the programming computer. This required developing a deeper understanding of OTA concepts, firmware images, device-management workflows, and the interaction between the embedded device and the software used to transfer an update.

To make the result of a firmware update visually identifiable, separate firmware versions were developed with different observable behavior. The baseline firmware and modified firmware were designed so that successful execution of the updated image could be confirmed through changes in LED behavior. The modified V2 firmware incorporated a red blinking LED,

providing a straightforward physical indication that a different firmware image was executing after the update process.

The intended customer-facing workflow involved generating the required firmware image and transferring the updated .bin file wirelessly using the TI SimpleLink Connect mobile application. Code and supporting content for this workflow were developed during the project. However, the intended mobile workflow encountered a technical issue that prevented the complete process from being reliably validated before the internship ended. The issue was not treated simply as an application failure; additional investigation and discussion with coworkers were required to understand the update process and determine alternative methods of validating the implementation.

With assistance from coworkers, OTA functionality was tested using an alternative workflow involving an SMP server. This workaround allowed the underlying update process and firmware behavior to be tested even though the intended mobile workflow could not be fully validated. I also developed and demonstrated the approach requested for the project, but an issue affecting that workflow was still being investigated by the appropriate research and development personnel. Because the process did not operate reliably enough for a customer-facing demonstration, the technical content was developed but a final publishable video using that workflow was not completed before the end of the internship.

Although the third project did not reach the same publication stage as the first two videos, it required the greatest amount of technical investigation into the underlying update process. Troubleshooting the OTA implementation required distinguishing between firmware behavior, update configuration, transfer mechanisms, and limitations in the available workflow. As a result, the project significantly expanded my understanding of OTA firmware updates and

reinforced the importance of validating a technical process before presenting it as a developer-facing solution.

4.5 Technical Validation, Review, and Publication Process

Validation occurred throughout all three major projects. Technical content could not be considered complete solely because a demonstration worked or a presentation had been created. The information also had to be technically accurate, reproducible, understandable to the intended audience, and consistent with the capabilities of the hardware and software being presented.

The BLE Mesh project relied heavily on review from other team members because the deliverable was intended to introduce a complex technology in a short format. The approximately eight presentation revisions required repeated verification of both technical content and messaging. The Zephyr BLE project added functional validation because the code modifications, BLE communication, and physical LED behavior all needed to operate as described. The OTA project required additional validation because a firmware update demonstration could not be presented as complete if the intended update path was not reproducible.

Feedback therefore became part of the engineering process rather than simply a final review step. Over the course of the internship, I learned to separate feedback concerning technical correctness from feedback concerning presentation preference and to evaluate conflicting recommendations based on the objective of the project. I also became more comfortable explaining the reasoning behind a technical or communication decision rather than assuming every requested change needed to be incorporated.

For resources intended for external publication, completed material proceeded through TI's internal submission and review workflow. Both the BLE Mesh video and Zephyr BLE

demonstration were submitted through JIRA by the end of the internship. The publication process provided additional experience with the level of review required before technical material can be released to developers and customers.

4.6 Technical Communication and Customer-Facing Application

Technical communication was practiced not only through the video projects but also through presentations, discussions with engineers, and two sales simulations completed at different points during the internship. The first sales simulation occurred approximately three to four weeks into the internship, while the second occurred around week nine. Conducting the exercise twice provided an opportunity to apply the technical knowledge accumulated throughout the summer and compare how my approach changed over time.

The simulations required understanding customer needs, determining which technical information was relevant to those needs, and communicating why a TI solution should be considered. This required a different communication approach from the technical videos. Rather than explaining every feature of a technology, the goal was to identify the information that mattered to the customer and connect technical capabilities to the customer's application.

By the second simulation, my manager specifically noted improvement in both my technical knowledge and my ability to communicate with a customer and position TI's solution. This progression demonstrated that the technical research performed throughout the internship could be applied beyond the individual video projects.

Communication skills were also developed through interactions with engineers throughout TI. I met individually with 20 people across different roles, teams, and technical areas, which required learning how to approach people with different areas of expertise and adapt questions accordingly. These interactions helped me understand that effective engineering

communication includes not only being able to explain a solution, but also being able to identify the correct person to ask, clearly describe a technical problem, and ask a sufficiently focused question to obtain useful information.

5. Results

The internship resulted in the completion of multiple developer-facing technical resources, functional embedded demonstrations, and significant growth in wireless connectivity knowledge and technical communication. Of the three primary video projects assigned during the internship, two were completed and submitted through TI's JIRA review process by the final day of the internship. The third project progressed through technical development and demonstration but did not reach final video submission because of an unresolved issue affecting the intended OTA workflow. Beyond the video deliverables, the internship resulted in practical experience with BLE, BLE Mesh, Zephyr, OTA firmware updates, embedded development tools, technical troubleshooting, and customer-facing engineering communication.

The progression of the three projects also demonstrated an increase in technical complexity throughout the internship. The first project required independently learning and communicating an unfamiliar wireless technology, while the second applied that knowledge through embedded software modification and hardware validation. The third project required deeper investigation of firmware-update mechanisms and troubleshooting a workflow that did not behave as expected. Together, these projects provided measurable outcomes in both technical development and the ability to communicate engineering concepts.

5.1 BLE Mesh Technical Resource

The first major result was the completion of the introductory BLE Mesh video. The project began with no previous BLE Mesh knowledge and only a high-level project objective. By

the end of the project, I had developed sufficient understanding of BLE Mesh to explain its network architecture, node functionality, scalability, security, applications, and TI's supporting resources in a concise developer-facing format.

Following approximately eight rounds of presentation revision and additional review of the completed content, the BLE Mesh video was finalized and submitted through JIRA for publication on TI.com. The completed resource represented not only a video deliverable but also the development of technical knowledge that did not exist at the beginning of the internship. The final material explained concepts including Proxy, Relay, Friend, and Low Power Nodes and connected these concepts to applications such as building automation, smart lighting, and grid infrastructure.

The project also produced an important improvement in my approach to technical assignments. Because the initial project direction did not define the required technical content, I had to learn how to establish the scope of an unfamiliar project, determine what information was relevant to the intended audience, and refine that information through technical review. This process provided a foundation that made the subsequent projects more efficient.

5.2 Zephyr BLE Demonstration

The second major result was a functional Zephyr BLE demonstration using the CC2340R53. Starting from the Zephyr Bluetooth LE Peripheral example, I modified the application to add functionality that allowed the development board's onboard LED to be controlled wirelessly through the TI SimpleLink Connect mobile application.

The completed application successfully established BLE communication between the CC2340R53 and the mobile application and responded to values written through the appropriate BLE characteristic. The resulting physical LED response provided a visible method of validating

that the modified embedded application was functioning correctly. This demonstrated my ability to move beyond running an existing software example by modifying source code, incorporating GPIO functionality, building and flashing firmware, and verifying the resulting hardware behavior.

The project also resulted in increased familiarity with the Zephyr development environment and embedded debugging tools. Development-environment failures, including the Linux reinstall and OpenOCD issue, required troubleshooting beyond the original demonstration requirements. Resolving these issues allowed development to continue and strengthened my ability to distinguish between application-level problems and problems associated with the development environment or toolchain.

By the final day of the internship, the Zephyr BLE demonstration and associated video were completed and submitted through JIRA. This represented the second of the three primary technical videos to reach the internal submission stage.

5.3 Zephyr BLE OTA Development

The third project resulted in the development and testing of a Zephyr BLE OTA firmware-update demonstration. Multiple firmware versions were developed with distinguishable behavior so that execution of an updated firmware image could be verified visually. The modified V2 firmware used a blinking red LED as an observable indication that the updated firmware was executing.

The project also resulted in a substantially deeper understanding of OTA firmware updates, including firmware-image generation, wireless transfer, device-management concepts, and the role of SMP within the update process. Although the intended SimpleLink Connect mobile workflow could not be fully validated before the internship ended, the underlying OTA

functionality was tested using the alternative SMP-server workflow with assistance from coworkers.

The third video did not reach final submission through JIRA because the intended customer-facing workflow was not sufficiently reliable for a publishable demonstration. However, the project resulted in functional firmware, OTA testing and troubleshooting, and completed technical content. Rather than presenting an unreliable process as complete, the limitation was identified and investigated while the relevant R&D work continued. As a result, the project still produced a significant technical outcome even though it did not reach the same publication stage as the first two projects.

5.4 Technical and Customer Communication Development

The results of the internship extended beyond the three video projects. Two sales simulations provided a direct opportunity to evaluate improvement in translating technical knowledge into customer-facing communication. The first simulation occurred approximately three to four weeks into the internship, while the second occurred around week nine.

By the second simulation, my manager noted significant improvement in both my technical knowledge and my ability to communicate with a customer and position TI's solution. This demonstrated progress in identifying which technical details were most relevant to a particular customer rather than presenting information without considering the customer's application or needs.

I also met individually with 20 people across different technical roles, teams, and areas of TI. These interactions expanded my understanding of applications engineering, systems engineering, product marketing engineering, and different connectivity organizations. More importantly, these discussions improved my ability to identify appropriate technical resources

and subject-matter experts, communicate what I had already investigated, and ask more focused questions when encountering a technical problem.

5.5 Technical and Professional Growth

One of the most significant results of the internship was the progression from having no previous wireless-connectivity experience to being able to research, develop, troubleshoot, and communicate BLE- and Zephyr-based applications. At the beginning of the internship, technologies such as BLE Mesh, Zephyr, and OTA firmware updates were unfamiliar. By the end of the internship, I had used these technologies in technical resources and functional embedded demonstrations while becoming increasingly comfortable navigating unfamiliar development environments.

Feedback received throughout the internship also changed my approach to engineering work. During the first half of the internship, I sometimes spent too much time attempting to solve blockers independently before communicating them. Midterm feedback identified proactivity, technical depth, and results-oriented execution as areas for continued development. During subsequent projects, I became more deliberate about identifying the specific problem I was experiencing, determining when independent troubleshooting was no longer productive, and seeking assistance from the appropriate engineer.

The internship also helped clarify the type of engineering work I would like to pursue. I enjoyed the customer-facing and technical communication aspects of Product Marketing Engineering, particularly when they required understanding a customer's technical needs and explaining an appropriate solution. However, I found that I was most interested in assignments involving hands-on development, debugging, and deeper investigation of embedded software. As a result, the internship strengthened my interest in pursuing technically focused roles such as

Applications Engineering or Software Engineering, where I can continue developing technical depth while retaining opportunities to collaborate with customers and other engineers.

Appendix A – Employment Verification Letter

Texas Instruments Incorporated
13532 N. Central Expressway,
Dallas, TX 75243

Verification of Employment for Amna Malik
6119 Cypresswood Dr
Spring, TX 77379

To Whom it May Concern,

Please accept this letter as confirmation that Amna Malik accepted an offer with Texas Instruments Incorporated and starts employment on June 1, 2026, ending August 21, 2026. Amna met all the contingencies required for their employment.

- Holds position of Requisition Product Marketing Engineering Intern in Dallas, TX
- Work Location: 12500 TI Boulevard 75243
- Performs the following duties: Conducting market studies for the products you are supporting. Providing product training for the sales channels. Analyzing revenue associated with key parts within your products groups. Providing forecast information by product family. Conducting analysis of the web presence for your products to enable customers better interface with TI. Participating in new product launch activities and ensuring customers and the worldwide sales force are aware of new product introductions for the products assigned. Working closely with development and business teams to evaluate product development strategies and market development needs
- Earns a salary rate of $31.50/hourly payable bi-weekly.
- Works on a full-time basis of forty hours per week.

If you have any questions or require additional information, please give me a call at the below number.

Best regards,

Anthony Oyebanjo | Talent Acquisition - Employment Verification
